Abstract—In this paper, we introduce a framework for automatic generation of dynamic equations for modular self-reconfigurable robots. The equations for kinematics and dynamics are generated recursively in two steps by using geometrical formulations and recursive Newton-Euler method. This framework has the purpose to analyse the kinematics and dynamics for serial as well as for branched multibody robot topologies with different dyad structures. A multi-functional and easy to use graphical interface provides functionalities such as the assembly of topologies, visual feedback of trajectories and parameters editing. Two benchmark examples show, that the proposed framework results coincide with the results produced by classical Lagrangian method.

Keywords—multi-body kinematics and dynamics; self-adaptive systems; automatic model generator.

I. INTRODUCTION

Self-reconfigurable modular robots [1] open a spectrum of applications especially in dangerous and hazardous environments [2]. Self-reconfiguration is necessary when robots are operating completely autonomously without human intervention. Modular systems are on the one hand advantageous in comparison to specialized systems because they are adaptable to different situations and applications; however on the other hand, the complexity for modelling and control can grow rapidly.

In classical mechanics, dynamical systems are usually described by setting up the equations of motion. The most common methods in the robotics are Newton-Euler, Lagrange, and Hamilton [3] formulations, all ending up with equivalent sets of equations. Different formulations may better suit for analysis, teaching purposes or efficient computation on robot.

Lagrange’s equations, for example, rely on energy properties of mechanical systems considering the multibody system as a whole [4]. This method is often used for study of dynamics properties and analysis in control design.

More applicable on real robots are the Newton-Euler formulation of dynamics. In this method, the dynamic equations are written separately for each body. This formation consists of two parts describing linear (Newton) and angular (Euler) motion [5].

In case of modular reconfigurable multibody systems obtaining of equations of motions can be a challenging and time consuming task. In this paper we use a method using geometric formulation of the equation of motion originally introduced by Park and Bobrow [6]. This method is based on recursive formulation of robot dynamics using recursive Newton-Euler combined with mathematical calculus of Lie groups and Lie algebras. The description of motion is based on twist and wrenches summarizing angular and linear velocities as well as applied forces and moments in six-dimensional vectors.

In this approach, the Newton’s second law \( F = ma \) and Euler’s equations are applied in two recursions: the forward (outward) and the backward (inward) recursion. Therefore, we speak about two-step approach. In the forward recursion the velocities and accelerations of each link are iteratively propagated from a chosen base module to the end-links of multibody system. During the backward recursion the forces and moments are propagated vice versa from the end-link to the base forming the equations of motions step-by-step. Recursive derivation of the equations makes it applicable to different types of robot geometries and moreover allows automatizing the process. There exist several publications generalizing this method for variety of applications [7], [8], [9]. Most of efficient results use Newton-Euler algorithms, for example Luh, Walker, and Paul [10] expressing the equations of motion in local link reference frames and by doing this reduce the complexity from \( O(n^3) \) to \( O(n) \). This approach was lately improved by Walker and Orin [11] providing more efficient recursive algorithm. Featherstone [12] proposed the recursive Newton-Euler equations in terms of spatial notation by combining the linear and angular velocities and wrenches into six dimensional vectors (Plücker notation). His ‘Articulated Body Inertia’ (ABI) approach becomes widely accepted in current research and is also of complexity \( O(n) \).

In the projects Symbrion [14] and Replicator [15], we develop autonomous modular reconfigurable robots that are capable to build multi-robot organisms by aggregating/disaggregating into different topologies [2]. In this paper we orientate our approach on the method proposed by Chen and Yang [16], which allows generating the motion equations in closed form based on Assembly Incidence Matrix (AIM) representation for serial as well as for tree-structured modular robot assemblies. The approach has been adapted to modular robots Backbone and Scout, because the geometry of modules differs from those proposed by Chen and Yang.

The paper is organized in the following way. In Section II, we give basic theoretical background about geometrical formulation for rigid body transformations. In Section III, we describe how the robot kinematics can be formulated for modular robots. In Section IV, robot assembly representation technique is introduced. Section V contains the recursive
approach for calculation of dynamics equations. In order to evaluate the approach a graphical user interface (GUI) called MODUROB is built and is explained in Section VI. Finally, Sections VII concludes the work and gives a short outlook.

II. THEORETICAL BACKGROUND

For kinematics analysis two Lie groups play an important role, the Special Euclidean Group $SE(3)$ and the Special Orthogonal Group $SO(3)$. $SE(3)$ group of rigid body motions consist of matrices of the form

$$
\begin{bmatrix}
R & p \\
0 & 1
\end{bmatrix},
$$

(1)

where $R \in SO(3)$ is the group of $3 \times 3$ rotation matrices and $p \in \mathbb{R}^{3 \times 1}$ is a vector.

Lie algebra is also an important concept associated with the Lie groups. Lie algebra of $SE(3)$, denoted as $se(3)$, is a tangent space at the identity element of $G$. It can be shown that the Lie algebra of $SE(3)$ consists of matrices of the form

$$
\begin{bmatrix}
\dot{\omega} & v \\
0 & 0
\end{bmatrix} \in \mathbb{R}^{4 \times 4},
$$

(2)

where

$$
\dot{\omega} = \begin{bmatrix}
0 & -\omega_z & \omega_y \\
\omega_z & 0 & -\omega_x \\
-\omega_y & \omega_x & 0
\end{bmatrix}.
$$

(3)

Lie algebra is defined together with the bilinear map called Lie bracket, which satisfy following conditions:

- Skew-symmetry: $[a, b] = -[b, a]$.
- Jacobi identity: $[a, [b, c]] + [c, [a, b]] + [b, [c, a]] = 0$

If elements are square matrices, the Lie bracket is a matrix commutator $[A, B] = AB - BA$.

The connection between Lie Group $SE(3)$ and Lie algebra $se(3)$ is the exponential mapping, which maps $se(3)$ onto $SE(3)$. Exponential mapping allows an elegant way to formulate rigid body motions. The formula originates from the solution of the time-invariant linear differential equation for velocity $\dot{p}$ of a point that rotates about an axis $\omega$

$$
\dot{p}(t) = \omega \times p(t) = \hat{\omega} p(t).
$$

(4)

By integrating the equation we receive

$$
p(t) = e^{\hat{\omega} t} p(0),
$$

(5)

where $p(0)$ is the initial position at $t = 0$ of the point. $\hat{\omega} \in so(3)$ is a skew symmetric matrix and the $e^{\hat{\omega} t}$ is the so-called matrix exponential

$$
e^{\hat{\omega} t} = I + \hat{\omega} t + \frac{(\hat{\omega} t)^2}{2!} + \frac{(\hat{\omega} t)^3}{3!} + \ldots
$$

(6)

Considering rotations with unit velocity ($\|\omega\| = 1$), the net rotations can be formulated as follows:

$$
e^{\hat{\omega} t} = I + \hat{\omega} t + \frac{\hat{\omega}^2}{2!} t^2 + \frac{\hat{\omega}^3}{3!} t^3 + \ldots
$$

(7)

Using the Rodrigues’ formula, a closed-form expression of this formula can be obtained without computing the full matrix exponent and therefore more efficient from the computational point of view.

$$
e^{\hat{\omega} t} = I + \hat{\omega} t + \sin q + \hat{\omega}^2 (1 - \cos q).
$$

(8)

The robot kinematics can be obtained by using the fact that rigid body motion can be achieved by a rotation about an axis combined with a translation parallel to it (Chasles’s Theorem) [17].

In this case, the exponential mapping $e^{q\hat{\omega}}$ can be interpreted as an operator that transforms a rigid body from their initial pose to new pose combining rotations and translations at the same time

$$
g_{ab}(q) = e^{q\hat{\omega}} g_{ab}(0),
$$

(9)

where $g_{ab}(0) \in SE(3)$ is an initial pose and $g_{ab}$ is the final pose. A twist associated with a screw motion is formulated as

$$
s_i = \begin{bmatrix}
-\omega_x \times p_i \\
\omega_i
\end{bmatrix} = \begin{bmatrix}
v_i \\
\omega_i
\end{bmatrix},
$$

(10)

where $\omega \in \mathbb{R}^{3 \times 1}$ is a unit vector showing in the direction of the twist axis and $q_i \in \mathbb{R}^{3 \times 1}$ is an arbitrary point on the axis. Revolute joints perform only pure rotations about an axis. Therefore the twist has the form:

$$
s_i = \begin{bmatrix}
0 \\
\omega_i
\end{bmatrix}.
$$

(11)

Analogous, the pure translation is much simpler,

$$
s_i = \begin{bmatrix}
v_i \\
0
\end{bmatrix},
$$

(12)
where \( v_i \in \mathbb{R}^{3 \times 1} \) is a unit vector facing in the direction of translation.

Linear mapping between an element of a Lie group and its Lie algebra can be performed by the adjoint representation. When \( X \) is given by \( X = (R, p) \in SE(3) \), then the adjoint map \( Ad_X : se(3) \mapsto se(3) \) acting on \( y \in se(3) \) is defined by \( Ad_X (y) = XyX^{-1} \). In [8] is also shown that \( Ad_X (y) \) admits the \( 6 \times 6 \) matrix representation

\[
Ad_X (y) = \begin{bmatrix} R & \hat{p}R \\ 0 & R \end{bmatrix} \begin{bmatrix} v \\ \omega \end{bmatrix},
\]

where \( \hat{p} \) is the skew-symmetric matrix representation of \( p \in \mathbb{R}^3 \). Linear mapping between an element of Lie algebra and its Lie algebra can be performed via the Lie bracket

\[
ad_x(y) = [x,y]
\]

(14)

Given \( x = (v_1, \omega_1) \in se(3), \) and \( y = (v_2, \omega_2) \in se(3), \) the adjoint map admits corresponding \( 6 \times 6 \) matrix representation

\[
ad_x(y) = \begin{bmatrix} \hat{\omega}_1 \\ 0_{3 \times 3} \\ \hat{\omega}_1 \end{bmatrix} \begin{bmatrix} v_2 \\ \omega_2 \end{bmatrix}.
\]

(15)

Similar to twists that contain angular and linear velocities in one vector, wrenches or general forces are described in a similar way. Wrenches are vector pairs containing forces (angular components) and moments (rotational component) acting on a rigid body.

\[
F = \begin{bmatrix} f \\ \tau \end{bmatrix},
\]

(16)

where \( f \in \mathbb{R}^3 \) is a linear force component and \( \tau \in \mathbb{R}^3 \) represents a rotational component. In contrast to general velocities as elements of \( se(3) \), wrenches are acting on \( se(3)^* \), the dual space and therefore behaves as covectors. For this reason wrenches transform differently under a change of coordinates by using so called adjoint transformation,

\[
F_x = Ad_x^T F_b,
\]

where forces acting on the body coordinate frame \( B \) are written with respect to coordinate frame \( A \). In spatial representation, this is equivalent as if the coordinate frame \( A \) were attached to the object.

III. ROBOT KINEMATICS

In modular reconfigurable systems the robot kinematics varies according to modules that are connected to each other. In homogeneous systems with the same physical parameters the kinematics depends only on the orientations of modules relative to each other. Such modular design is advantageous for autonomous systems. Using heterogeneous modules the complexity grows with the number of different modules that are used. Therefore, in most cases we assume identical or similar structure of the modules with similar physical properties. Both robots have been designed with similar geometry, same docking units and differ mostly in several insignificant properties such as number of sensors, different sensors or actuators. Nevertheless, even if the differences are not crucial, we speak about heterogeneous modules because of the additional Degree of Freedom (DOF) in Scout robot that is able to rotate the docking element even if only in limited way. Table I summarizes the mechanical properties of Backbone and Scout modular robots.

<table>
<thead>
<tr>
<th>Module Types</th>
<th>Cubic Link Modules (Chen)</th>
<th>Backbone / Scout (Symbrion / Replicator)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Joint Types</td>
<td>homogeneous (large/small)</td>
<td>revolute, prismatic</td>
</tr>
<tr>
<td>DOFs</td>
<td>rot.: ±180°</td>
<td>Backbone: bend.:±90°; Scout: bend.:±90°, rot.: ±180°</td>
</tr>
</tbody>
</table>

Using only revolute joints without any prismatic joints simplify additionally the autonomous and recursive model generator for kinematics and finally for the dynamics model.

A. Dyad Kinematics

Dyad dependencies are common in recursive formulations because the calculation proceeds from one module to the next comprising only two modules. The calculation is done from the base module to all pendant links. In the approach proposed by Chen and Yang [16], a dyad is defined as two adjacent modules \( (v_i, \omega_i) \) connected by a joint \( \epsilon_i \) (Figure 2(a)). A link assembly is defined by taking one of those modules (link) together with one joint. The relative position and orientation of one frame attached to one module with respect to next frame in the second module can be described under joint displacement by a homogeneous \( 4 \times 4 \) matrix \( H_{ij}(q) \in SE(3) \):

\[
H_{ij}(q_j) = H_{ij}(0) e^{\hat{q}_j},
\]

(18)

where \( \hat{q}_j \in se(3) \) is the twist of joint \( e_j \) and \( q_j \) is the angle of rotation. The relative position and orientation between the modules can be recognized by the robot through different kind of on-board sensors such as accelerometers, compass or by vision system. In project Symbion and Replicator the geometry of the Backbone (Figure 1(a)) and Scout (Figure 1(b)) robots differ from modules proposed by Chen and Yang. Backbone and Scout modules consist of two moving parts and one main hinge motor placed inside of each module and for this reason already implies a complete dyad as defined by Chen and Yang in each robot. In order to adapt the recursive kinematics approach to Backbone and Scout robot we need to extend the system boundaries of a dyad (Figure 2(b)). Since the most weight is concentrated in the middle of the modules where the main motors are placed, the attached coordinate frames for each module coincide with the centre of mass. Because of two robots and hence two revolute joints in a dyad only one joint is involved into calculation in each recursive step.
the calculation from a chosen base module to each pendant end-link in all branches. One possibility how the connecting order can be obtained is to use the AIM proposed by Chen and Yang [16]. For branched type of robots, two traversing algorithms are common to find the shortest paths: the Breadth-first search (BFS), and the Depth-first search (DFS) algorithms. The forward kinematic transformations for the branched robot configuration starting from base to each of the pendant links $a_n$ of path $k$ with $m$ branches can be formulated as follows:

$$H(q_1, q_2, \ldots, q_n) = \left[ \begin{array}{c} H_1 \\ H_2 \\ \vdots \\ H_k \\ \vdots \\ H_m \end{array} \right] = \prod_{i=1}^{m} (H_{a_i, l_{ai}}(0)e^{q_{ai}g_{ai}}),$$ \hspace{1cm} (20)

where $H(q_1, q_2, \ldots, q_n)$ represent all poses of all pendant end-links by using homogeneous 4x4 matrix representation.

IV. ROBOT ASSEMBLY REPRESENTATIONS

Matrix notation is a powerful method to represent modular robots kinematic dependencies. The most common matrices used in robotics are the Adjacency and the Incidence matrix. Both matrices represent the connections between the neighbouring nodes. In [16], Chen proposes a method based on AIM that allows to represent the whole robot assembly consisting from links and joints additionally carrying the information about the type of robot and about used joints. A dynamic model for modular robot assembly is created autonomously from the AIM. This method was developed for a homogeneous kind of robots varying only in size with different joint possibilities including revolute or prismatic joints. Scout and Backbone robots contain only revolute joints however the number is not limited to one DOF. Therefore, the approach proposed in [16] cannot be directly used for this kind of modules and need to be adapted.

A. Adapted Assembly Incidence Matrix

The Backbone and the Scout robots are both cubic shaped robots, however provide only four sides that are equipped with docking units. Therefore, using the notation of gaming dice only ports 2 - 5 are able to set a connection. A difference between modular robots proposed in [16] and the Scout/Backbone modules is that joints are not considered as a separate mechanical parts (joint modules), which are required to connect two modules, but rather are placed inside each of the modules. For these reasons each robot builds a full dyad already.

For simplicity, we allow docking only in horizontal plane and we also use the principle of gaming dice for side notations. Robot organisms have to go into initial configuration when additional robots decide to dock. Using this assumption, we distinguish between three major dyad configuration classes: the serial DS, the parallel DP and the orthogonal DO dyad.
class, where the second letter determines the axes of rotation of module $j$ with respect to module $i$. A serial coupled dyad (DS) is given when the axes of rotation are in one line. When the rotational axes are parallel than the dyad becomes a member of a parallel class (DP). Finally, when the axes are orthogonal to each other, the robots are classified as the orthogonal to each other connected robot assembly (DO). This information can be easily extracted from the matrix and used for direct computation. Additionally, the symmetry of the platform allows neglecting the sign of the orientation because it does not affect the calculation. Table II summarizes all possible configurations considering that top and bottom side of the robots and hence the sides 1 and 6 of a gaming dice do not contain docking units.

**TABLE II**  
DYADS LOOK-UP TABLE FOR SCOUT AND BACKBONE.

The autonomous docking procedure is based either on IR sensor communication or also can be fulfilled by using vision system [20], [21]. Backbone and the Scout robots have one revolute joint as a major actuator, therefore the information about the kind of actuators in the last row of the AIM is unnecessary. Instead, we use the last row for the three types of docking orientations for serial, parallel or orthogonal case. The last column in the AIM contains the information about the kind of actuators in the last row of the AIM is unnecessary. Instead, we use the last row for the three types of docking orientations for serial, parallel or orthogonal case.

B. Direct/Indirect Recursive Transformations

Structuring the kinematics dependencies into an AIM$_{SB}$, we are able to apply the transformations $T_{ij}$ between the modules directly once the AIM is determined. By reusing the already calculated dependencies that are stored into lists it is fast and efficient to calculate the kinematics for big robot organisms. We use two lists: one list containing transformation results between consecutive joints, we call it a Direct-Transformation-List (DTL) and another list called Indirect-Transformation-List (IDTL) for non-consecutive transformations between joints however still in the same kinematics path.

In DTL as shown in Table III, each line represents one direct transformation. The first two columns indicate the connected modules and the last two columns hold the information, which sides are connected. IDTL contains the indirect transformations, which are calculated by two successive transformations ($T_{ij} = T_{ik} \cdot T_{kj}$). The first two columns denote the desired transformation. Next four columns hold two multiplied transformations that are stored in DTL or in IDTL. Both tables refer to the example shown in Figure 4.

**TABLE III**  
DIRECT AND INDIRECT TRANSFORMATION LISTS.

A short example demonstrates the first traversing calculations using both lists:

$$T_{01} = T_{01}(0)e^{j\varphi_{01}} \quad \text{direct}$$
$$T_{12} = T_{12}(0)e^{j\varphi_{12}} \quad \text{direct}$$
$$T_{02} = T_{01} \cdot T_{12} \quad \text{indirect} \quad (21)$$

This algorithm can be compared with DFS algorithm, providing a flexible way to calculate the order in which all
possible transformations can be calculated during runtime.

The flowchart of the algorithm is illustrated in Figure 6.

V. MODULAR ROBOT DYNAMICS

In general, two main branches of robot dynamics problems are mostly considered, namely the forward and the inverse dynamics problems. Forward dynamics play an important role in simulation of multibody systems, also called as direct dynamics. Forward dynamics problem determines accelerations and external reaction forces of the system giving initial values for positions, velocities and applied internal/external forces, whereas the inverse dynamics problem determines the applied forces required to produce a desired motion. The first problem that appears in modular self-reconfigurable robotics is that the model of the robot assembly cannot be known a priori. Therefore, the robot should be able to generate its own model autonomously without human intervention.

A. Recursive Two-Step Approach

The original idea for recursive formulation and computation of the closed form equation of motion was introduced by Park and Bobrow [6]. The idea was extended by Chen and Yang by introducing the AIM. Starting with the AIM, that contains the information about how robots are assembled, the formulation of equations of motion is done in two steps: first applying forward transformation from base to the end-link, followed by the second recursion backwards from the end-link to the base module. Finally, we get the equation of motion in a closed-form. Before starting the recursion, some assumption and initializations should be done. In the first step, the system has to choose the starting module denoted as the base module. Starting from this module, the AIM is filled based on path search algorithms such as BFS or DFS. After the AIM is built and all paths are determined the recursive approach can be started.

• Initialization: Given \( V_0, \dot{V}_0, F^n_{n+1} \)

\[
V_b = V_0 = (0 \ 0 \ 0 \ 0 \ 0)\ T \\
\dot{V}_b = \dot{V}_0 = (0 \ 0 \ g \ 0 \ 0)\ T
\]

• Forward recursion: for \( i = 1 \) to \( n \) do

\[
H_{i-1, i} = H_i e^{i\dot{q}_i} \\
V_i = A_d H_{i-1, i} (V_{i-1}) + S_i \dot{q}_i \\
\dot{V}_i = A_d H_{i-1, i} (\dot{V}_{i-1}) - ad_{ad} H_{i-1, i} (V_{i}) + S_i \ddot{q}_i
\]

where \( V_b \) and \( V_0 \) denote generalized velocities expressed in the starting frame 0 and all other quantities are expressed in link frame \( i \). \( F_{n+1} \) is the force acting on the end-link of chained robots. This values can either be estimated or read from force sensors attached to the robots.

• Backward recursion: for \( i = n \) to \( 1 \) do

\[
F_i = A_d H_{i+1, i} (F_{i+1}) - F^e_i + M_i \ddot{V}_i - ad_d^i (M_i V_i) \\
\tau_i = S_i^T F_i
\]

Here, \( M_i \) is the generalized mass matrix of the form

\[
M_i = \begin{bmatrix}
I & 0 \\
0 & m I_3
\end{bmatrix}
\]

where \( I \) is \( 3 \times 3 \) inertia matrix and \( I \) is the identity matrix. The non-diagonal terms are zero because in our case the center of mass coincides with the origin. \( F_i \) is the total generalized force traversed from link \( i - 1 \) to \( i \) consisting of internal and external wrenches and \( \tau_i \) is the applied torque by the corresponding actuator.

B. Equations of Motion

By expanding the recursive equations (25) to (28) in body coordinates, it can be shown that the equations for generalized velocities, generalized accelerations and forces can be obtained in matrix form:

\[
V = T S \dot{q} \\
\dot{V} = T H_0 V_0 + T S \ddot{q} + T \dot{ad}_q V \\
F = T^T F^e + T^T M V + T^T \dot{ad}_q^* M V \\
\tau = S^T F
\]
where

\[
\dot{q} = \text{column}[q_1, q_2, \ldots, q_n] \in \mathbb{R}^{n \times 1}
\]

\[
\ddot{q} = \text{column}[\dot{q}_1, \dot{q}_2, \ldots, \dot{q}_n] \in \mathbb{R}^{n \times 1}
\]

\[
V = \text{column}[V_1, V_2, \ldots, V_n] \in \mathbb{R}^{6n \times 1}
\]

\[
V = \text{column}[\dot{V}_1, \dot{V}_2, \ldots, \dot{V}_n] \in \mathbb{R}^{6n \times 1}
\]

\[
F = \text{column}[F_1, F_2, \ldots, F_n] \in \mathbb{R}^{6n \times 1}
\]

\[
F^e = \text{column}[F^e_1, F^e_2, \ldots, F^e_n] \in \mathbb{R}^{6n \times 1}
\]

\[
\tau = \text{column}[\tau_1, \tau_2, \ldots, \tau_n] \in \mathbb{R}^{n \times 1}
\]

\[
S = \text{diag}[S_1, S_2, \ldots, S_n] \in \mathbb{R}^{6n \times n}
\]

\[
M = \text{diag}[M_1, M_2, \ldots, M_n] \in \mathbb{R}^{6n \times 6n}
\]

\[
ad_{S\dot{q}_i} = \text{diag}[-ad_{S\dot{q}_1}, -ad_{S\dot{q}_2}, \ldots, -ad_{S\dot{q}_i}] \in \mathbb{R}^{6n \times 6n}
\]

\[
ad_{\dot{V}_i} = \text{diag}[-ad_{\dot{V}_1}, -ad_{\dot{V}_2}, \ldots, -ad_{\dot{V}_i}] \in \mathbb{R}^{6n \times 6n}
\]

The index \( n \) represents the number of elements containing also virtual joints that are required to move the robot in a space [22].

\[
T_{H_0} = \begin{bmatrix}
\text{Ad}_{H_{0,1}}^{-1} \\
\text{Ad}_{H_{0,2}}^{-1} \\
\vdots \\
\text{Ad}_{H_{0,n}}^{-1}
\end{bmatrix} \in \mathbb{R}^{6n \times 6}
\]

\[
T = \begin{bmatrix}
I_{6 \times 6} & 0_{6 \times 6} & 0_{6 \times 6} & \cdots & 0_{6 \times 6} \\
\text{Ad}_{H_{1,2}}^{-1} & I_{6 \times 6} & 0_{6 \times 6} & \cdots & 0_{6 \times 6} \\
\text{Ad}_{H_{1,3}}^{-1} & \text{Ad}_{H_{2,3}}^{-1} & I_{6 \times 6} & \cdots & 0_{6 \times 6} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\text{Ad}_{H_{1,n}}^{-1} & \text{Ad}_{H_{2,n}}^{-1} & \text{Ad}_{H_{3,n}}^{-1} & \cdots & I_{6 \times 6}
\end{bmatrix} \in \mathbb{R}^{6n \times 6n}
\]

Both examples (Figure 7) show absolutely identical behaviour with examples implemented based on Lagrangian equations as well as with the geometrical approach based on twist and wrenches and therefore evaluates the approach.

\[
M(q)\ddot{q} + C(q, \dot{q})\dot{q} + N(q) = \tau
\]

\[
M(q) = \dot{S}T^TMTS
\]

\[
C(q, \dot{q}) = \dot{S}T^T(M\dot{ad}_{\dot{S}\dot{q}} + \dot{ad}_{\dot{V}})TS
\]

\[
N(q) = \dot{S}T^TMT\dot{H}_0\dot{V} + \dot{S}^TTF^e
\]

VI. MODUROB - MODULAR ROBOTICS SOFTWARE TOOL

MODUROB is a tool built in MATLAB® that contains a possibility to build robot topologies by simply clicking on Topology Matrix Grid (Figure 8). Currently, two types of robots are provided: the Backbone (Figure 1(a)) and the Scout robot (Figure 1(b)). For simplification, robots are only allowed to assemble or disassemble in planar configurations on the ground. The automatic model can be built in two ways: analytically or numerically. The symbolic formulation in MATLAB is done by using the symbolic toolbox. For solving of differential equations the user can choose between the numerical integrators that are provided by MATLAB. In order to move the robot in a joint space, different gait generators are provided either using rhythmic generators based on rhythm functions [22] or gait generators that use chaotic map. We use an approach proposed in [23], that allows to generate periodic gaits that result from synchronization effects of coupled maps. Such approach can help to control complex multibody structures by mapping the active joints to an individual chaotic driver [24].

Both examples (Figure 7) show absolutely identical behaviour with examples implemented based on Lagrangian equations as well as with the geometrical approach based on twist and wrenches and therefore evaluates the approach.

VII. CONCLUSION AND FUTURE WORK

In this paper, we demonstrate a MATLAB framework that allows analysing the kinematics and dynamics of modular robots. The calculation of self-adaptive models is based on recursive geometrical approach built on Screw Theory [26]. The proposed algorithm is inspired by the work from Chen and Yang and has been modified and adapted to the needs of robot
modules developed in projects Symbion and Replicator. Such tool can not only be used for studying of topology behaviours of modular robots but also open a easy way to understand the theory behind the geometrical recursive approach. After we are able to build the models for kinematics and dynamics autonomously the next step will be to investigate different control design strategies such as feedback linearisation, self-organized and learning control mechanisms.

ACKNOWLEDGMENT

The “SYMBRION” project is funded by the European Commission within the work programme “Future and Emergent Technologies Proactive” under the grant agreement no. 216342. The “REPLICATOR” project is funded within the work programme “Future and Emergent Technologies Proactive” under the grant agreement no. 216240.
